Abstract

Background: Skeletal dysplasia and osteochondrodysplasia refer to a genetically and clinically heterogeneous group of disorders of skeletal development and growth. Their prevalence is about 1 in 4000 births. Skeletal dysplasia is prevalent worldwide and its prevalence varies in different parts of the world and even in the same country varies from region to region. The objective is to study the prevalence of skeletal dysplasia based on clinico-radiological features. **Subjects and Methods:** A hospital retro prospective based study of skeletal dysplasia's was conducted over a period of 2 years in which 100 cases of skeletal dysplasia's were studied and were grouped according to international classification of osteochondrodysplasia' s revised in 2006. **Results:** 100 cases of skeletal dysplasia's were detected by various modes of examination like clinical, radiological (radiographs, USG, CT scan, MRI, echocardiography), genetic and biochemical tests. Among 100 cases 22 cases showed clinico-radiologically concordance, 45 cases showed clinico-radiological complement and 40 cases showed clinico-radiological discordance. **Conclusion:** Our study makes an important observation that only clinical evaluation detected only 20% of skeletal dysplasia's; and hence the importance of clinic-radiological evaluation in the proper diagnosis of skeletal dysplasia's.

Introduction

Dysplasia is a developmental abnormality; in the pathology, size, shape and organization of adult cells.[1]Osteochondrodysplasia s are a broad category of heterogeneous disorders comprising of bone or cartilage abnormalities or structure. A number of over 350 diseases are associated with the osteochondrodysplasia and dysostasis.[2] Their genetic variants tend to evolve during their lives. They exist due to genetic variants. Skeletal dysplasia therefore varies from dysostoses that include malformations of single or several bones attributable to pathological in-utero blastogenesis and remain unchanged throughout the lifespan phenotypically.[3] Today more than 450 entities focused on radiological, molecular and biochemical parameters have been identified.[4] Although certain dysplasia's are quite rare individually, in various epidemiological studies, their overall prevalence as a group was 2.3–7.6 in 10 000 births.[5–8]

Few dysplasia's become fatal at perinatal level. They arise in non-lethal dysplasia with extreme small height or inability to attain longitudinal development or certain physical deformities in the early childhood. The condition is observed on antenatal ultrasound scans. Dysplasia may be accurately identified based on the combination of clinical and family history, physical assessment, radiological evaluation and molecular and biochemical testing. One of the main elements of a diagnostic study of dysplasia is the radiology assessment. A general radiologist will often find a patient with suspected skeletal dysplasia in a series of x-rays. While certain dysplasia's can quickly be identified on the basis of some features or what are regarded as textbook results, a careful approach to diagnostics is important. In this article, we discuss the radiological method for the diagnosis of non-lethal dysplasia and identify the radiological features of many significant and more severe non-lethal dysplasia's afterwards.

Subjects and Methods

Place of Study: Department of Radiology, Niloufer Hospital for women and children.

Type of Study: It is a hospital based Cross sectional study with consecutive sampling.

Duration: Two Years i.e. January 2018 to December 2019.

Sample Size: 100 Children.

Inclusion criteria:

- All the cases of skeletal dysplasia's referred to the department of radio diagnosis
- Skeletal dysplasia cases detected at birth during the study period.
- Cases with skeletal dysplasia were included irrespective of the age and sex.

Exclusion criteria:

- Patients who don't meet the criteria of definition of skeletal dysplasia parse.
- Those patients who refuse to be included in the study.

Informed consent from all the patients was taken before undergoing the study. All cases of skeletal dysplasia referred to the department of radio- diagnosis and all the consecutive births were screened for presence of skeletal dysplasia's, after studying family history, genetic history, obstetric history, antenatal history. The cases underwent a detailed anthropometric measurement like height, weight, upper segment length, lower segment length, upper segment to lower segment ratio, head circumference, chest circumference.

Method of Examination:

All cases referred to the department of Radio- diagnosis with high degree of clinical suspicion of skeletal dysplasia were evaluated with skeletal survey as per the recommendation by Wynne-Davies 30.

They included:

1. Skull X-ray lateral view.
2. Antero-Posterior and lateral view of spine (T1-S1).
3. Chest Posterior -Anterior view including shoulders.
4. Pelvis/hips.
5. Antero-Posterior view of one knee.
6. Antero-Posterior view of one forearm.
7. Posterior-Anterior view of hand/ wrist
8. Feet Antero-Posterior view including ankle.

For new born and small babies, Antero-Posterior and lateral film of the whole body was taken (infantogram).

Results

This study was performed to detect skeletal dysplasia prevalence and categorization in the latest International Nosology 20063 of patients with skeletal dysplasia's in new-born's and to relate clinical diagnosis to radiological diagnosis.

Table 1: Age and sex wise distribution of skeletal dysplasia's

Age group	Total
Abortus / Stillborn	03
Neonates	23
Infants	11
1-4 years	15
4-8 years	22
8-12 years	06
12 years and above	20
Total	**100**
Sex	
Male	56
Female	44

Table 2: Showing distribution of cases based on consanguinity

Total no. Of cases	Consanguineously married couples	Non-consanguineously married couples
100	48	52

The number of cases examined for skeletal dysplasias showed a very high degree of consanguinity majority being uncle-niece marriage.

Type 2 Collagen group, Filamin and FGFR3 group, Lysosomal storage disease with skeletal development were observed majorly in the entire study population.

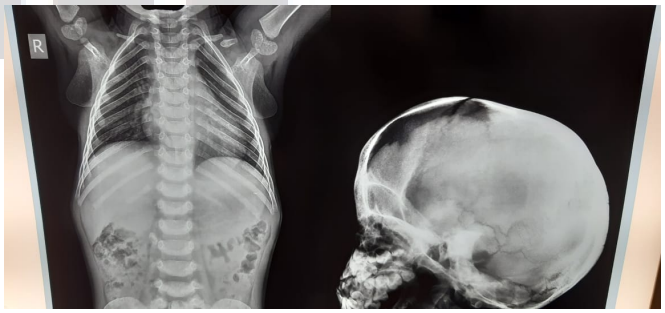

Figure 1: Cleido Cranial Dysplasia

100 cases of skeletal dysplasia's were detected by various modes of examination like clinical, radiological (radiographs, USG, CT scan, MRI, echocardiography), genetic and biochemical tests. Among 100 cases 22 cases showed clinico-radiologically concordance, 45 cases showed clinico-radiological complement and 40 cases showed clinico-radiological discordance.

Table 3: Classification of skeletal dysplasias based on international nosology 2006

Serial. No	Groups	No. of cases	Percentage
I.	**Filamin Group**	**16**	**16%**
A)	Fronto Metaphyseal Dysplasia's	03	3.0 %
B)	OPD Syndrome	05	5.0 %
C)	Larsen Syndrome	08	8.0 %
II	**FGFR3 Group**	**11**	**11%.**
A)	Thanatophoric Dysplasia	02	2.0 %
B)	Achondroplasia	09	9.0 %
III	**Type 2 Collagen Group**	**12**	**12 %**
A)	Spondylo Epiphyseal Dysplasia Congenita	03	3.0 %
B)	Spondylo Epiphyseal Dysplasia	02	2.0 %
C)	Mild Sped with Premature Onset Arthrosis	06	6.0 %
D)	Stickler Syndrome	01	1.0 %
IV	**Sulphation Disorders**	**03**	**3%**
A)	Multiple Epiphyseal Dysplasia's	03	3.0 %
V	**Short Rib Dysplasia Group**	**09**	**9 %**
A)	Ellisvan Crevald Syndrome	03	3.0 %
B)	Asphyxiating Thoracic Dysplasia	06	6.0 %
VI	**Metaphyseal Dysplasia**	**05**	**5 %**
A)	Cartilage Hair Hypoplasia	03	3.0 %
B)	Metaphyseal Dysplasia with Pancreatic Insuffi-ciency Cyclic Neutropenia	02	2.0 %
VII	**Spondylo Metaphyseal Dysplasia**	**03**	**3 %**
VIII	**Severe Spondylodysplastic Dysplasia**	**02**	**2 %**
A)	Fibrochondrogenesis	02	2.0 %
IX	**Acromelic Dysplasias**	**04**	**4 %**
A)	Trichorhinophalangeal Syndrome Type I	02	2.0 %
B)	Trichorhinophalangeal Syndrome Type II	02	2.0 %
X	**Mesomelic And Rhizo-mesomelic Dysplasia**	**06**	**6 %**
A)	Robinow Syndrome	06	6.0%
XI	**Slender Bone Dysplasia**	**02**	**2 %**
A)	Kenny Caffey Dysplasia	02	2.0 %
XII	**Increased Bone Density Group**	**08**	**8%**
A)	Osteopetrosis	06	6.0%
B)	Pyknodysostosis	02	2.0%
XIII	**Limb Hypoplasia-reduction Group**	**9**	**9%**
	FHUFS	06	6.0%
	Tar Syndrome	03	3.0%
XIV	**Lysosomal Storage Disease with Skeletal Involvement.**	**11**	**11%**
	MPS Type - 1	06	6.0%
	MPS Type - 3	04	4.0%
	MPS Type - 4	01	1.0%

Figure 2: Asphyxiating thoracic dysplasia

Figure 3: Ellis van crevald syndrome

Table 4: Correlation between clinical diagnosis and radiological diagnosis:

Variables	No. of Cases	Percentage
Clinico-radiological concordance	22/139	22.0%
Clinico-radiological complement	45/139	45.0%
Clinico-radiological discordance	40/139	40.0%

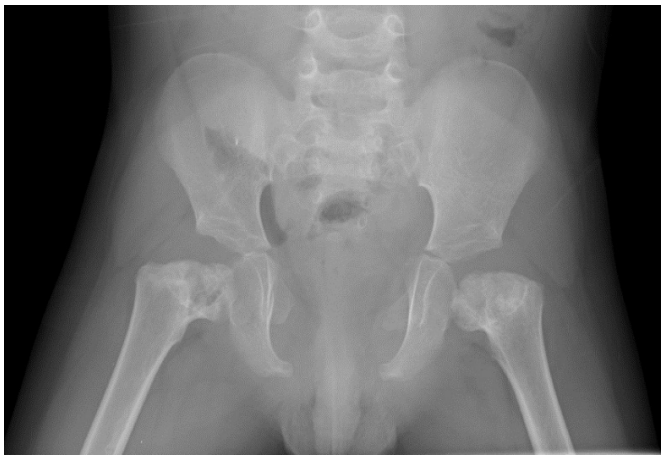

Figure 4: Metaphyseal Chondrodysplasia

Figure 5: Metaphyseal Chondrodysplasia

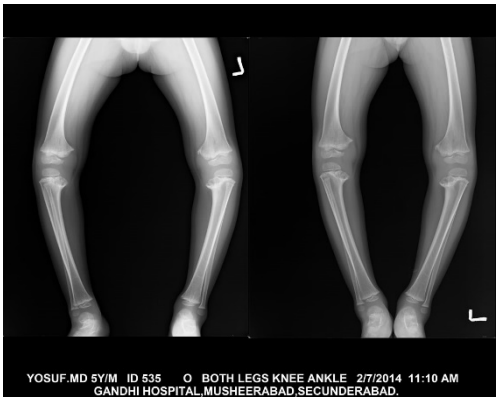

Figure 6: Metaphyseal Chondrodysplasia

Our study makes an important observation that only clinical evaluation detected only 20% of skeletal dysplasia's; and hence the importance of clinic-radiological evaluation in the proper diagnosis of skeletal dysplasia's.

Table 5: Diagnostic accuracy in clinical diagnosis of MPS & SPED

Clinical	Radiological diagnosis		Total
	MPS	Others	
MPS	6	4	10
Others	7	83	90
Total	13	87	100
Sensitivity- 45%		Specificity-98%	
	SPED	Others	
SPED	1	8	SPED
Others	8	83	OTHERS
Total	9	91	TOTAL
Sensitivity- 11%		Specificity-25%.	

Among 100 cases of skeletal dysplasia's detected in our study period, most common group of dysplasia was mucopolysaccharidosis with as many as 10 cases. Among those 6 cases were detected clinically with a sensitivity of 45% and specificity of 98%. Sped was the next common group of skeletal dysplasia in our study period with as many as 9 cases detected, among those clinical diagnosis was possible in only 1 case with sensitivity of 11% and specificity of 25%.

Discussion

A complete study on dysplasia's in the population is difficult because majority of skeletal dysplasia's are nonlethal, many of which do not manifest at birth and may go unnoticed. Even those with major manifestations, there are difficulties in logistics with population-based studies.

All the cases in our study were classified according to the latest Nosology 2006 revision.[9] Majority of our cases satisfied the classification. We have included these cases, because of majority of skeletal dysplasia's and syndromes overlap and have a common pathogenetic mechanism ex. Stickler syndrome, which was once considered as syndrome is now included under dysplasia's. We strongly believe that our cases which could not fit into the classification system may be included in classification system in near future. A very few Indian studies have been conducted on this.[10–12]

Among 100 cases of skeletal dysplasia's which were detected by various methods of examination like clinical, radiological (Radiography, USG, CT, MRI, echocardiography), genetic

and biochemical tests. Among these 100 cases, 22 cases showed clinico-radiological concordance, 40 cases showed clinico-radiological complement and 45 cases showed clinico-radiological discordance. This shows that diagnosis of skeletal dysplasia's cannot be made just on clinical grounds or purely on radiological basis. This reemphasises the fact that multidisciplinary approach is more appropriate for arriving at a diagnosis in skeletal dysplasia's as in any other condition.

We were not able to show the accuracy of clinical diagnosis in all the cases, because majority of cases detected were individual cases, so we tried to include the most common skeletal dysplasia group like MPS, SPED. Diagnostic accuracy of clinical diagnosis in MPS- We had 11 cases of MPS, among which 5 cases were detected on clinical grounds with a sensitivity of 45% and specificity of 98%, but diagnosis was possible in all cases by radiological examination. However, with recent development of enzyme replacement therapy (ERT) the clinico-radiological diagnosis will and soon become obsolete & only enzymatic diagnosis will be required to help these patients with ERT. Diagnostic accuracy of clinical diagnosis in SPED- SPED (9 cases) was the next common entity and the diagnosis on clinical grounds was possible in one case with sensitivity of 11% and specificity of 25% but radiological diagnosis was possible in all cases. This shows that in majority of cases an accurate diagnosis of skeletal dysplasia's is only possible on radiological evaluation.

Conclusion

Skeletal dysplasia's are common group of disorders; they have a varied presentation, right from antenatal period to adult life. They can present with Deformity, Dwarfism, Disability and Death. These groups of disorders are not unknown but are difficult to diagnose and manage. It requires a multidisciplinary approach to identify and manage such disorders. It is ideal to have national registry of such disorders.
